ever need to use a capacitor on a grounded wall? I am having trouble understanding why someone would use a capacitor on a
grounded wall in the first place. I have been reading why capacitors are used on power cables but I don't see how it would ever
be helpful to put a capacitor on a grounded wall. A basic rule of thumb I have been taught for voltages is the lower the voltage
the more capacitance is needed. For example, a 220V wall outlet needs a 1F capacitor to reduce the voltage down to 120V. This
makes sense because a lot of the voltage is being pulled from the wall wire. But, why would I ever want to apply a cap across a
grounded wire? A: For example, a 220V wall outlet needs a 1F capacitor to reduce the voltage down to 120V Let's say that the
plug is a bit worn out and is not fully grounded. As a result, every person can touch the hot to at most 120V, but is perfectly
safe. Now put a capacitor on the plug and an additional 120V on the cap, and the person can touch the outlet to anywhere
between 0V and 120V, and not feel anything. If the fault is in a ground wire, the ground wire may only be connected to the
ground, or to a metal box of some kind. As a result, you can hook it up, and someone touching it could get at most 120V, but not
quite at full 120V (e.g. because the ground is not a good conductor of electricity, so the actual ground is a bit lower on the wire
than what we can feel). However, the safety margin you get from touching the outlet to ground is significant, whereas touching
the outlet to the cap does not provide any safety benefit f678ea9f9e
